Abstract

Ruscogenin exerts an anti-inflammatory effect in the pathogenesis of various human diseases, including pulmonary hypertension, acute lung injury, acute pancreatitis and cerebral ischemia. Its role in isoflurane-induced rats with postoperative cognitive dysfunction (POCD) was investigated in this study. Aged rats were exposed to isoflurane for establishing a model of POCD, and administered with ruscogenin by gavage. Cognitive dysfunction was evaluated by the Morris water maze test. Hematoxylin and Eosin (H&E) staining was designed to assess neuronal damage. Markers of brain damage and neuroinflammation were detected by enzyme-linked-immunosorbent serologic assay. Isoflurane exposure caused impaired cognitive function by increasing escape latency, decreasing the time taken for crossing target and time in target quadrant. However, administration of ruscogenin reversed these cognitive dysfunctions. Abnormal morphological phenomena on neurons and enhanced levels of serum calcium-binding protein β (S-100β) and neuron-specific enolase (NSE) were identified in mice post-isoflurane exposure. Administration of ruscogenin ameliorated the neuronal morphological damages and reduced the levels of S-100β and NSE in the hippocampi of mice. Isoflurane-induced enhancements in the mRNA expression levels of NLRP3, ASC, IL-1β and IL-18 proteins were also restored by administration of ruscogenin. Ruscogenin exerted neuroprotective effects against isoflurane-induced cognitive dysfunction and neuroinflammation through blocking of NLRP3 pathway.

Keywords: ruscogenin; cognitive dysfunction; isoflurane; NLRP3 inflammasome; postoperative cognitive dysfunction

Introduction

Anesthetics, such as isoflurane (ISO) and sevoflurane, are widely used in surgical operations (Alwardt et al., 2005). However, the increasing incidences of complications associated with exposure to anesthetics have been reported recently (Belcher et al., 2017). Postoperative cognitive dysfunction (POCD) is a reversible neurodegenerative disease caused by anesthesia and surgery in elderly patients. POCD includes impairments in psychomotor speed, visual and spatial ability, executive function, information processing, memory, concentration and attention (Huang et al., 2020). Owing to POCD, medical expenses are increased, length of hospitalization is prolonged, and the overall life of patient is affected by it with increasing morbidity and mortality (Cui et al., 2018). Pathogenic factors,
including oxidative stress, neuroinflammation, decline in neurogenesis and neuron apoptosis, have been demonstrated to contribute to the pathogenesis of POCD (Shao et al., 2020). Therefore, drugs or rehabilitation therapies that regulate balance in neurotransmitters, cause reduction in neuroinflammation, and result in the suppression of neuron apoptosis, have been widely used in the treatment of POCD (Wang et al., 2021a).

Ruscogenin (RUS), the primary effective steroid sapogenin discovered in *Ophiopogon japonicus*, was first isolated from *Ruscus aculeatus*, which has been widely used in the treatment of acute and chronic inflammatory diseases (Lu et al., 2014a). For example, ruscogenin exerted antifibrotic and anti-inflammatory effects to attenuate streptozotocin-induced diabetic nephropathy (Lu et al., 2014b). Monocrotaline-induced pulmonary hypertension (Bi et al., 2013), cerulein-induced acute pancreatitis (Ercan et al., 2019) and particulate matter-induced acute lung injury (Wang et al., 2021b) were ameliorated by ruscogenin through its anti-inflammatory capacity. Cerebral ischemic-induced inflammatory pathway was also suppressed by ruscogenin (Guan et al., 2013), and ruscogenin alleviated ischemia/reperfusion-induced blood–brain barrier dysfunction (Zhang et al., 2020). Since surgery is indicated to promote the secretion of pro-inflammatory factors and blood–brain barrier dysfunction to induce neuroinflammation during the development of POCD (Hovens et al., 2016), the role of ruscogenin in anesthetic-induced POCD was investigated in this study.

Isoflurane, a halogenated hydrocarbon inhalation anesthetic, induces neuropathological sensitive tissue lesions, inflammation and apoptosis of hippocampal cells, and is also depicted to exert neurotoxic effects on the nervous system (Lin & Zuo, 2011). Isoflurane-induced cognitive dysfunction and neuroinflammation were used to construct the animal model of POCD (Cao et al., 2018). This study investigated the effects of ruscogenin on isoflurane-induced cognitive dysfunction and neuroinflammation as well as demonstrated the underlying mechanism.

Materials and methods

Animal model

A total of 80 male Sprague–Dawley mice (80-week old; weight 250–280 g) were purchased from SLAC Laboratory Animal Technology Co. Ltd. (Shanghai, China). The animals were maintained individually in pathogen-free cages with free access to water and food. The study was approved by the Ethics Committee of Pingxiang People’s Hospital, and was in accordance with National Institutes of Health Laboratory Animal Care and Use Guidelines. The animals were grouped as follows: control (N = 20), isoflurane (ISO, N = 20), ISO + 1 mg/kg ruscogenin (RUS, N = 20), and ISO + 3 mg/kg ruscogenin (N = 20). Mice in the control group received room air; those in the ISO group were exposed to 2% isoflurane (Sigma-Aldrich, San Francisco, CA, USA) for 4 h; and the ones in the ISO + RUS groups were first exposed to isoflurane and then administered 1 or 3 mg/kg of ruscogenin (J&K Scientific Ltd., Beijing, China) through intragastric route. Five rats in each group were decapitated under anesthesia of 35 mg/kg sodium pentobarbital. After 24 h of ruscogenin administration, the animal brains were harvested and conducted with the following analyses. The remaining 15 rats in each group were subjected to the Morris water maze test (MWM).

Morris water maze test

After 24 h post-administration of ruscogenin, mice were trained in a circular tank (tank diameter: 150 cm and height: 70 cm) with hidden platform (diameter: 10 cm), which was located 2 cm below the surface of water. Mice were placed in four equal hypothetical quadrants with four points (North, East, South and West), and were subjected to swim to record the time taken (latency) to find the hidden platform by video camera mounted above the water maze. Mice were trained for five days, and the platform was removed on the sixth day to test route length to find platform, time taken for crossing target, and time in target quadrant for 2 min. The data were recorded and analyzed by the image analysis system connected to the camera.

Hematoxylin and Eosin (H&E) staining

The hippocampi of brain tissues isolated from mice were immersed in 4% paraformaldehyde, and then embedded in paraffin. The tissues were sliced into 4-μm sections, and the sections were used for Hematoxylin and Eosin staining before prior to microscopic observations (Leica Microsystems, Wetzlar, Germany).

Enzyme-Linked-Immunosorbent Serologic Assay (ELISA)

The hippocampi were incubated with RIPA lysates buffer (Beyotime, Beijing, China) and centrifuged at 12,000 g for 1 h. The supernatant was harvested, and the protein concentration was determined by Pierce™ BCA Protein Assay Kit (Thermo Fisher Scientific, Waltham, MA, USA). Levels of serum calcium-binding protein β (S-100β), neuron-specific enolase (NSE), Interleukin (IL)-1β, IL-6 and tumor necrosis factor alpha (TNF-α) were measured using enzyme-linked immunosorbent assay (ELISA) kit.
factor-alpha (TNF)-α were measured using commercial kits (Nanjing Biotechnology Co. Ltd., Nanjing, China).

Western blot test

Protein samples from hippocampi were separated by 10% sodium dodecyl sulfate–polyacrylamide gel electrophoresis (SDS-PAGE), and transferred onto nitrocellulose membrane. The membrane was blocked and probed with specific antibodies: anti-NLR family pyrin domain containing 3 (NLRP3), anti-apoptosis-associated speck-like protein (ASC) (1:2,000; Abcam, Cambridge, UK), anti-IL-1β, anti-IL-18 (1:2,500; Abcam) and anti-glyceraldehyde 3-phosphate dehydrogenase (GAPDH) (1:3,000; Abcam). Following incubation with horseradish peroxidase-conjugated secondary antibody (1:4,000; Abcam) and tetramethylbenzidine, the protein bands were visualized using chemiluminescence (Sigma-Aldrich).

Statistical analysis

All data in at least triple replicates were expressed as mean ± SEM, and analyzed by Student’s t-test or one-way analysis of variance (one-way ANOVA) under the SPSS software. P < 0.05 was considered as statistically significant.

Results

Ruscogenin ameliorated isoflurane-induced cognitive dysfunction

Mice were exposed to isoflurane, and the Morris water maze test demonstrated that the representative route length of mice to find the platform increased in the isoflurane group as compared to that in the control group (Figure 1A). However, administration of ruscogenin decreased the route length in the isoflurane group (Figure 1A). Moreover, the escape latency was enhanced in rats post-isoflurane exposure (Figure 1B), while ruscogenin reduced the escape latency (Figure 1B). Isoflurane-induced impairment of memory, which was evidenced by the decreased time taken for crossing target (Figure 1C) and time in target quadrant (Figure 1D), was raised by the administration of ruscogenin. Therefore, ruscogenin improved the long-term spatial learning and ability to memorize in isoflurane-treated mice.

Ruscogenin ameliorated isoflurane-induced neuronal damage

Morphological analysis of the hippocampi demonstrated a relatively large cell body in the control group.

Discussion

Chinese medicinal herbs, with antioxidant, anti-inflammatory and anti-apoptotic capacities, have been widely used for the prevention of cognitive dysfunction of POCD (Chu et al., 2018). *Ophiopogon japonicus* has been demonstrated as a pharmacological Chinese medicinal herb in distinct diseases, including diabetes, cancers and inflammatory diseases (Chen et al., 2016). Since ruscogenin, the primary effective steroid sapogenin from *Ophiopogon japonicus*, has been reported to ameliorate ischemic-induced inflammatory pathway (Guan et al., 2013) or blood–brain barrier dysfunction (Zhang et al., 2020), its role in POCD was investigated in the present study.

A former study has pointed that cognitive dysfunction caused by anesthetics is a challenging problem for post-surgery patients (Belrose and Noppens, 2019). Patients with POCD suffer from abstract thinking, decreased social activities and persistent impairment of memory (Johnson et al., 2002). It has been reported that isoflurane increased the incidence of POCD in patients compared to propofol (Geng et al., 2017), and also

Scale bars = 100 μm. (B) Ruscogenin administration attenuated isoflurane-induced enhancements in the levels of S-100β and NSE in rats. ***vs. control, *P* < 0.001. @, @@@ vs. ISO, *P* < 0.05, *P* < 0.001.](image-url)
induced cognitive deficits in aged mice (Wu et al., 2015). In this study, mice were exposed to isoflurane to establish a model of POCD. Results indicated that isoflurane induced cognitive impairment in aged mice, while ruscogenin reversed the results by reducing escape latency, time taken for crossing target and time in target quadrant, thereby indicating its role in improving long-term spatial learning and memory abilities in isoflurane-treated mice. Moreover, abnormal morphological phenomena in the neurons were also observed in the hippocampi of mice post-isoflurane exposure. The plasma levels of both S-100β and Aβ1-40 proteins were upregulated in POCD.
patients post-isoflurane (Geng et al., 2017). This study has consistently demonstrated that isoflurane upregulated S-100β and NSE levels in aged mice. However, administration of ruscogenin attenuated neuronal damage and reduced levels of S-100β and NSE, suggesting that ruscogenin protected hippocampal neurons against isoflurane-induced neuronal damage in aged mice.

Increasing evidence has indicated that surgery or anesthesia-induced neuroinflammation is the major contributor of POCD (Safavynia and Goldstein, 2019). Levels of IL-1β, IL-6, and TNF-α were significantly upregulated in POCD patients exposed to isoflurane compared to those exposed to propofol (Geng et al., 2017). Isoflurane induced neuroinflammation, thus contributing to cognitive impairment in aged mice (Cao et al., 2018). Ruscogenin reduced the levels of TNF-α and IL-1β to attenuate cerebral ischemic injury (Guan et al., 2013). Here, ruscogenin also attenuated isoflurane-induced increase in the levels of IL-1β, IL-6 and TNF-α in aged mice, thus exerting anti-inflammatory effect against POCD. Oxidative stress is implicated in the pathogenesis of POCD, and strategies to modulate oxidative stress and inflammation have been widely used in the mitigation of POCD (Ho et al., 2020). The potential antioxidant role of ruscogenin in isoflurane-induced mice must be investigated in the future studies.

NLRP3 inflammasome, containing NLRP3, ASC and caspase-1, functions as an innate immune sensor and participates in cell death, including pyroptosis, ferroptosis, necroptosis and apoptosis (Huang et al., 2021). Aberrant activation of NLRP3 inflammasome is involved in inflammatory diseases, Alzheimer's disease, diabetes and cancers (Huang et al., 2021). Overactivation of NLRP3 inflammasome contributes to the progression of POCD (Zhao et al., 2021). NLRP3 inflammasome regulates the activation of caspase-1 and mediates the maturation and secretion of IL-1β and IL-18, thus associating with neuroinflammation and oxidative stress during progression of POCD (Wei et al., 2019). Activation of NLRP3 inflammasome was also found to be associated with isoflurane-induced cognitive impairment and inflammation in aged mice (Wang et al., 2018). Suppression of NLRP3 inflammasome activation attenuated isoflurane-induced pyroptosis and cognitive impairment (Fan et al., 2018). Importantly, ruscogenin suppressed the activation of NLRP3 inflammasome to ameliorate blood–brain barrier dysfunction caused by cerebral ischemia (Cao et al., 2016). This study established that increased protein expression levels of NLRP3, ASC, IL-1β and IL-18 in the hippocampi of mice post-isoflurane exposure were reversed by administration of ruscogenin. Therefore, administration of NLRP3 inflammasome inhibitor, ruscogenin, might have ameliorated isoflurane-induced cognitive impairment and reduced pyroptosis in aged mice.

In summary, ruscogenin demonstrated neuroprotective effect against isoflurane-induced cognitive impairment and neuroinflammation via repression of NLRP3/caspase-1 pathway, thus providing a novel therapeutic strategy for POCD treatment.
